The intervertebral ranges of motion (ROM) of the thoracolumbar spine (TLS) have been measured using segmental angle measurement (SAM) and photodensitometry (PD). The SAM has the advantage of being a valid and reliable method. However, due to the extremely close sagittal alignment of the vertebral body and the intervertebral disc of the cervical and thoracic spine, the measurements using the SAM are found to be less accurate in cervical and thoracic spine. PD has been used to measure the ROM in the transverse plane, but has the disadvantage of relying on the existence of the intervertebral disc and the epidural space, which are lacking in degenerative changes. The purpose of this study was to establish a new method for measuring the ROM in sagittal plane. The spinal column of 31 volunteers was measured by both SAM and PD. The ROM in the sagittal plane was measured as the difference between the flexion angle of C7-T1 and that of T1-S1 and was expressed as a fraction of the range of flexion of the thoracolumbar spine. The results showed that the range of spinal flexion was 78.65% of the flexion of thoracolumbar spine. This new measurement method is both valid and reliable. It has the advantage of not relying on the presence of the intervertebral disc and epidural space.A security researcher has discovered a security vulnerability in Google Chrome that allows unauthenticated remote code execution.
